Definition 1 (Linear Separability)

Two sets of feature vectors, \( X_0, X_1 \), sampled from a \( p \)-dimensional feature space \( X \), are called linearly separable if \( p+1 \) real numbers, \( w_0, w_1, \ldots, w_p \), exist such that the following conditions hold:

1. \( \forall x \in X_0: \sum_{j=0}^{p} w_j x_j < 0 \)
2. \( \forall x \in X_1: \sum_{j=0}^{p} w_j x_j \geq 0 \)
**Multilayer Perceptron Basics**

**Definition 1 (Linear Separability)**

Two sets of feature vectors, $X_0, X_1$, sampled from a $p$-dimensional feature space $X$, are called linearly separable if $p+1$ real numbers, $w_0, w_1, \ldots, w_p$, exist such that the following conditions hold:

1. $\forall x \in X_0: \sum_{j=0}^{p} w_j x_j < 0$
2. $\forall x \in X_1: \sum_{j=0}^{p} w_j x_j \geq 0$
The XOR function defines two sets in the $\mathbb{R}^2$ that are not linearly separable:

<table>

→ Specification of several hyperplanes.
→ Layered combination of several perceptrons: the multilayer perceptron.
Multilayer Perceptron Basics

(1) Overcoming the Linear Separability Restriction

A minimum multilayer perceptron $y(x)$ that can handle the XOR problem:

\[ x_0 = 1 \rightarrow \quad y_0^n = 1 \rightarrow \quad y = \begin{cases} 1 & \text{if } x_1 = 0 \\ -1 & \text{if } x_1 = 1 \end{cases} \]

\[ x_1 \rightarrow \quad \sum \quad \rightarrow \quad \{-, +\} \]

\[ x_2 \rightarrow \quad \sum \quad \rightarrow \quad \{-, +\} \]

\[ x_2 = 1 \quad x_3 \quad x_4 \]

\[ x_2 = 0 \quad - x_1 \quad + x_2 \]

\[ x_1 = 0 \quad x_1 = 1 \]
Multilayer Perceptron Basics

Multilayer Perceptron Basics

(1) Overcoming the Linear Separability Restriction

A minimum multilayer perceptron $y(x)$ that can handle the $XOR$ problem:

$$W^h = \begin{bmatrix} -0.5 & -1 & 1 \\ 0.5 & -1 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ x_1 \\ x_2 \end{bmatrix}$$

$$\sum \{ -, + \}$$

$W^h_{20}$ $w^h_{21}$ $w^h_{22}$ $y^h_0 = 1$ $x_0 = 1$ $x_1$ $x_2$ $y(x)$ = heaviside($W^h_{0}(W^h_{1}x))$ $x_1 = 0$ $x_1 = 1$ $x_2 = 0$ $x_2 = 1$ $x_3$ $x_4$
Multilayer Perceptron Basics

(1) Overcoming the Linear Separability Restriction

A minimum multilayer perceptron $y(x)$ that can handle the **XOR** problem:

$$y(x) = \begin{cases} 
1 & x_1, x_4 \quad + \quad x_3 \\
0 & x_2 \\
1 & x_1 \\
1 & x_1 \\
\end{cases}$$

$$W^h = \begin{bmatrix} 
-0.5 & -1 & 1 \\
0.5 & -1 & 1 \\
\end{bmatrix} \begin{bmatrix} 
1 \\
x_1 \\
x_2 \\
\end{bmatrix}$$
Multilayer Perceptron Basics

(1) Overcoming the Linear Separability Restriction

A minimum multilayer perceptron \( y(x) \) that can handle the XOR problem:

\[
y(x) = \text{heaviside} \left( W^o \left( \text{heaviside}(W^h x) \right) \right)
\]

\[
W^h = \begin{bmatrix} -0.5 & -1 & 1 \\ 0.5 & -1 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ x_1 \\ x_2 \end{bmatrix}
\]

\[
W^o = \begin{bmatrix} 0.5 & 1 & -1 \end{bmatrix}
\]
The first, second, and third layer of the shown multilayer perceptron are called input, hidden, and output layer respectively. Here, in the example, the input layer is comprised of \( p+1=3 \) units, the hidden layer contains \( l+1=3 \) units, and the output layer consists of \( k=1 \) unit.

Each input unit is connected via a weighted edge to all hidden units (except to the topmost hidden unit, which has a constant input \( y_0^h = 1 \)), resulting in six weights, organized as \( 2 \times 3 \)-matrix \( W^h \). Each hidden unit is connected via a weighted edge to the output unit, resulting in three weights, organized as \( 1 \times 3 \)-matrix \( W^o \).

The input units perform no computation but only distribute the values \( x_0, x_1, x_2 \) to the next layer. The hidden units (again except the topmost unit) and the output unit apply the heaviside function to the sum of their weighted inputs and propagate the result.

The nine weights \( w = (w_1^h, \ldots, w_2^h, w_1^o, w_2^o, w_3^o) \), organized as \( W^h \) and \( W^o \), specify the multilayer perceptron (model function) \( y(x) \) completely: \( y(x) = \text{heaviside}(W^o (\text{Heaviside}(W^h x))) \)

The function \( \text{Heaviside} \) (with capital H) denotes the extension of the scalar \( \text{heaviside} \) function to vectors.

For \( z \in \mathbb{R}^d \) the function \( \text{Heaviside}(z) \) is defined as \( (\text{heaviside}(z_1), \ldots, \text{heaviside}(z_d))^T \).
The multilayer perceptron was presented by Rumelhart and McClelland in 1986. Earlier, but unnoticed, was a similar research work of Werbos and Parker [1974, 1982].

Compared to a single perceptron, the multilayer perceptron poses a significantly more challenging training (= learning) problem, which requires continuous (and non-linear) threshold functions along with sophisticated learning strategies.

Marvin Minsky and Seymour Papert in 1969 used the XOR problem to show the limitations of single perceptrons. Moreover, they assumed that extensions of the perceptron architecture (such as the multilayer perceptron) would be similarly limited as a single perceptron. A fatal mistake. In fact, they brought the research in this field to a halt that lasted 17 years. [Berkeley]
Multilayer Perceptron Basics

(2) Overcoming the Non-Differentiability Restriction

The sigmoid function $\sigma()$ as threshold function:

$$\sigma(z) = \frac{1}{1 + e^{-z}}$$

$$\frac{d\sigma(z)}{dz} = \sigma(z) \cdot (1 - \sigma(z))$$

A perceptron with a non-linear and differentiable threshold function:

$$\begin{align*}
x_0 &= 1 \\
x_1 \\x_2 \\
p \\
\sum_0 \\
y
\end{align*}$$
Multilayer Perceptron Basics

(2) Overcoming the Non-Differentiability Restriction (continued)

Computation of the perceptron output $y(x)$ with the sigmoid function $\sigma()$:

$$y(x) = \sigma(w^T x) = \frac{1}{1 + e^{-w^T x}}$$

An alternative to the sigmoid function is the $\text{tanh}()$ function:

$$\text{tanh}(z) = \frac{e^z - e^{-z}}{e^z + e^{-z}} = \frac{e^{2z} - 1}{e^{2z} + 1}$$
Remarks:

- Employing a nonlinear function as threshold function in the perceptron, such as sigmoid or heaviside, is a prerequisite to synthesize complex nonlinear functions via layered composition.

- Note that a single perceptron with sigmoid activation is identical with the logistic regression model function.

- The derivative of $\sigma()$ has a canonical form. It plays a central role for the computation of the gradient of the loss function in multilayer perceptrons. Derivation:

$$
\frac{d\sigma(z)}{dz} = \frac{d}{dz} \frac{1}{1 + e^{-z}} = \frac{d}{dz} (1 + e^{-z})^{-1} \\
= -1 \cdot (1 + e^{-z})^{-2} \cdot e^{-z} \cdot (-1) \\
= \sigma(z) \cdot \sigma(z) \cdot e^{-z} \\
= \sigma(z) \cdot \sigma(z) \cdot (1 + e^{-z} - 1) \\
= \sigma(z) \cdot \sigma(z) \cdot (\sigma(z)^{-1} - 1) \\
= \sigma(z) \cdot (1 - \sigma(z))
$$

Network with sigmoid units

No decision power beyond a single hyperplane

Nonlinear decision boundaries but no gradient information

Nonlinear decision boundaries and gradient information
Remarks (limitation of linear thresholds):

- A multilayer perceptron with linear threshold functions can be expressed as a single linear function and hence is equivalent to the power of a single perceptron only.

- Consider the following exemplary composition of three linear functions as a multilayer perceptron with \( p \) input units, two hidden units, and one output unit: \( y(x) = W^o [W^h x] \)

The weight matrices are as follows:

\[
W^h = \begin{bmatrix}
w^h_{11} & \cdots & w^h_{1p} \\
w^h_{21} & \cdots & w^h_{1p}
\end{bmatrix}, \quad W^o = \begin{bmatrix}
w^o_1 & w^o_2
\end{bmatrix}
\]

A straightforward derivation then yields:

\[
y(x) = W^o [W^h x] = \begin{bmatrix}
w^o_1 & w^o_2
\end{bmatrix} \begin{bmatrix}
w^h_{11} x_1 + \cdots + w^h_{1p} x_p \\
w^h_{21} x_1 + \cdots + w^h_{1p} x_p
\end{bmatrix}
\]

\[
= w^o_1 w^h_{11} x_1 + \cdots + w^o_1 w^h_{1p} x_p + w^o_2 w^h_{21} x_1 + \cdots + w^o_2 w^h_{1p} x_p
\]

\[
= (w^o_1 w^h_{11} + w^o_2 w^h_{21}) x_1 + \cdots + (w^o_1 w^h_{1p} + w^o_2 w^h_{1p}) x_p
\]

\[
= w^T x
\]
Multilayer Perceptron Basics
Unrestricted Classification Problems

Setting:
- $X$ is a multiset of feature vectors from an inner product space $X$, $X \subseteq \mathbb{R}^p$.
- $C = \{0, 1\}^k$ is the set of all multiclass labelings for $k$ classes.
- $D = \{(x_1, c_1), \ldots, (x_n, c_n)\} \subseteq X \times C$ is a multiset of examples.

Learning task:
- Fit $D$ using a multilayer perceptron $y()$ with a sigmoid activation function.

$W^o \in \mathbb{R}^{k \times (l+1)}$
Multilayer Perceptron with Two Layers

(1) Forward Propagation

Multilayer perceptron $y(x)$ with a hidden layer and $k$-dimensional output layer:

Model function evaluation (= forward propagation):

$$y(x) = \sigma \left( W^o y^h(x) \right) = \sigma \left( W^o \left( \frac{1}{\sigma} \left( W^h x \right) \right) \right)$$
Each input unit is connected to the hidden units $1, \ldots, l$, resulting in $l \cdot (p+1)$ weights, organized as matrix $W^h \in \mathbb{R}^{l \times (p+1)}$. Each hidden unit is connected to the output units $1, \ldots, k$, resulting in $k \cdot (l+1)$ weights, organized as matrix $W^o \in \mathbb{R}^{k \times (l+1)}$.

The hidden units and the output unit(s) apply the (vectorial) sigmoid function, $\sigma$, to the sum of their weighted inputs and propagate the result as $y^h$ and $y$ respectively. For $z \in \mathbb{R}^d$ the vectorial sigmoid function $\sigma(z)$ is defined as $(\sigma(z_1), \ldots, \sigma(z_d))^T$.

The parameter vector $w = (w^h_{10}, \ldots, w^h_{lp}, w^o_{10}, \ldots, w^o_{kl})$, organized as matrices $W^h$ and $W^o$, specifies the multilayer perceptron (model function) $y(x)$ completely: $y(x) = \sigma(W^o(\sigma(W^h x)))$.

The shown architecture with $k$ output units allows for the distinction of $k$ classes, either within an exclusive class assignment setting or within a multi-label setting. In the former setting a so-called “softmax layer” can be added subsequent to the output layer to directly return the class label $1, \ldots, k$.

The non-linear characteristic of the sigmoid function allows for networks that approximate every (computable) function. For this capability only three “active” layers are required, i.e., two layers with hidden units and one layer with output units. Keyword: universal approximator [Kolmogorov theorem, 1957]

Multilayer perceptrons are also called multilayer networks or (artificial) neural networks, ANN for short.
Multilayer Perceptron with Two Layers

\end{bmatrix} =
\begin{bmatrix}
    y_{11}^h & \ldots & y_{1n}^h \\
    \vdots & \ddots & \vdots \\
    y_{l1}^h & \ldots & y_{ln}^h \\
\end{bmatrix}$$

(b) Propagate $y_h$ from hidden to output layer:

$$W^o \in \mathbb{R}^{k \times (l+1)}$$

$$\begin{bmatrix}
    w_{10}^o & \ldots & w_{1l}^o \\
    \vdots & \ddots & \vdots \\
    w_{k0}^o & \ldots & w_{kl}^o \\
\end{bmatrix}
\begin{bmatrix}
    1 & \ldots & 1 \\
    y_{11}^h & \ldots & y_{1n}^h \\
    \vdots & \ddots & \vdots \\
    y_{l1}^h & \ldots & y_{ln}^h \\
\end{bmatrix} =
\begin{bmatrix}
    y_{11} & \ldots & y_{1n} \\
    \vdots & \ddots & \vdots \\
    y_{k1} & \ldots & y_{kn} \\
\end{bmatrix}$$
Multilayer Perceptron with Two Layers

(2) Backpropagation

The considered multilayer perceptron $y(x)$:

Parameters $w$:

$W^h \in R^{l \times (p+1)}$

$W^o \in R^{k \times (l+1)}$
Multilayer Perceptron with Two Layers

(2) Backpropagation

[linear regression] [mlp arbitrary depth]

The considered multilayer perceptron \( y(x) \):

\[ x_0 = 1 \rightarrow \cdots \rightarrow y^h_0 = 1 \rightarrow y^h_1 \rightarrow \cdots \rightarrow y_k \]

\( x_0 = 1 \) is the bias term.

\[ x = (\in \text{extended input space}) \]

\[ y = (\in \text{output space}) \]

\[ y^h = (\in \text{extended feature space}) \]

Parameters \( w \):

\[ W^h \in \mathbb{R}^{(p+1) \times l} \]

\[ W^o \in \mathbb{R}^{(l+1) \times k} \]

Calculation of derivatives (= backpropagation) wrt. the global squared loss:

\[ L_2(w) = \frac{1}{2} \cdot \text{RSS}(w) = \frac{1}{2} \cdot \sum_{(x,c) \in D} \sum_{u=1}^{k} (c_u - y_u(x))^2 \]
Multilayer Perceptron with Two Layers

(2) Backpropagation (continued)

$L_2(w)$ usually contains various local minima:

\[ y(x) = \sigma \left( W^o \left( \sigma \left( W^h x \right) \right) \right) \]

\[ L_2(w) = \frac{1}{2} \sum_{(x,c) \in D} \sum_{u=1}^{k} (c_u - y_u(x))^2 \]
Multilayer Perceptron with Two Layers

(2) Backpropagation (continued)

$L_2(w)$ usually contains various local minima:

$$y(x) = \sigma \left( W^o \left( \sigma^{1} \left( W^h x \right) \right) \right)$$

$$L_2(w) = \frac{1}{2} \sum_{(x,c) \in D} \sum_{u=1}^{k} (c_u - y_u(x))^2$$

$$\nabla L_2(w) = \left( \frac{\partial L_2(w)}{\partial w^o_{10}}, \ldots, \frac{\partial L_2(w)}{\partial w^o_{kl}}, \frac{\partial L_2(w)}{\partial w^h_{10}}, \ldots, \frac{\partial L_2(w)}{\partial w^h_{lp}} \right)^T$$
Multilayer Perceptron with Two Layers

(2) Backpropagation (continued)

$L_2(w)$ usually contains various local minima:

$y(x) = \sigma \left( W^o \left( \sigma \left( W^h x \right) \right) \right)$

$L_2(w) = \frac{1}{2} \sum_{(x,c) \in D} \sum_{u=1}^{k} (c_u - y_u(x))^2$

$\nabla L_2(w) = \left( \frac{\partial L_2(w)}{\partial w^o_{10}}, \ldots, \frac{\partial L_2(w)}{\partial w^o_{kl}}, \frac{\partial L_2(w)}{\partial w^h_{10}}, \ldots, \frac{\partial L_2(w)}{\partial w^h_{lp}} \right)^T$

(a) Gradient in direction of $W^o$, written as matrix:

$$
\begin{bmatrix}
\frac{\partial L_2(w)}{\partial w^o_{10}} & \cdots & \frac{\partial L_2(w)}{\partial w^o_{kl}} \\
\vdots & \ddots & \vdots \\
\frac{\partial L_2(w)}{\partial w^o_{k0}} & \cdots & \frac{\partial L_2(w)}{\partial w^o_{kl}}
\end{bmatrix} \equiv \nabla^o L_2(w)
$$

(b) Gradient in direction of $W^h$:

$$
\begin{bmatrix}
\frac{\partial L_2(w)}{\partial w^h_{10}} & \cdots & \frac{\partial L_2(w)}{\partial w^h_{1p}} \\
\vdots & \ddots & \vdots \\
\frac{\partial L_2(w)}{\partial w^h_{l0}} & \cdots & \frac{\partial L_2(w)}{\partial w^h_{lp}}
\end{bmatrix} \equiv \nabla^h L_2(w)
$$
Remarks:

- “Backpropagation” is short for “backward propagation of errors”. Backpropagation is a method of calculating the derivatives (the gradient).

- Basically, the computation of the gradient $\nabla L_2(w)$ is independent of the organization of the weights in matrices $W^h$ and $W^o$ of a network (model function) $y(x)$. Adopt the following view instead:

  To calculate $\nabla L_2(w)$ one has to calculate each of its components $\partial L_2(w) / \partial w$, $w \in w$, since each weight (parameter) has a certain impact on the global loss $L_2(w)$ of the network. This impact—as well as the computation of this impact—is different for different weights, but it is canonical for all weights of the same layer though: observe that each weight $w$ influences “only” its direct and indirect successor nodes, and that the structure of the influenced successor graph is identical for all weights of the same layer.

  Hence it is convenient, but not necessary, to process the components of the gradient layer-wise (matrix-wise), as $\nabla^o L_2(w)$ and $\nabla^h L_2(w)$ respectively. Even more, due to the network structure of the model function $y(x)$ only two cases need to be distinguished when deriving the partial derivative $\partial L_2(w) / \partial w$ of an arbitrary weight $w \in w$: (a) $w$ belongs to the output layer, or (b) $w$ belongs to some hidden layer.

- The derivation of the gradient for the two-layer MLP (and hence the weight update processed in the IGD algorithm) is given in the following, as special case of the derivation of the gradient for MLPs at arbitrary depth.
Multilayer Perceptron with Two Layers

(2) Backpropagation (continued) [linear regression] [mlp arbitrary depth]

(a) Update of weight matrix $W^o$:

$$W^o = W^o + \Delta W^o,$$

using the $\nabla^o$-gradient of the loss function $L_2(w)$ to take the steepest descent:

$$\Delta W^o = -\eta \cdot \nabla^o L_2(w)$$
Multilayer Perceptron with Two Layers

(2) Backpropagation (continued)  [linear regression]  [mlp arbitrary depth]

(a) Update of weight matrix $W^o$:

$W^o = W^o + \Delta W^o,$

using the $\nabla^o$-gradient of the loss function $L_2(w)$ to take the steepest descent:

$$\Delta W^o = -\eta \cdot \nabla^o L_2(w)$$

$$= -\eta \cdot \begin{bmatrix}
\frac{\partial L_2(w)}{\partial w^o_{10}} & \cdots & \frac{\partial L_2(w)}{\partial w^o_{1l}} \\
\frac{\partial L_2(w)}{\partial w^o_{k0}} & \cdots & \frac{\partial L_2(w)}{\partial w^o_{kl}}
\end{bmatrix}$$

$: [derivation]$

$$= \eta \cdot \sum_D \left[ (c - y(x)) \odot y(x) \odot (1 - y(x)) \right] \otimes y^h$$
(2) Backpropagation (continued) [mlp arbitrary depth]

(b) Update of weight matrix $W^h$:

$W^h = W^h + \Delta W^h,$

using the $\nabla^h$-gradient of the loss function $L_2(w)$ to take the steepest descent:

$\Delta W^h = -\eta \cdot \nabla^h L_2(w)$

\[
\Delta W^h = -\eta \cdot \begin{bmatrix}
\frac{\partial L_2(w)}{\partial w_{10}^h} & \cdots & \frac{\partial L_2(w)}{\partial w_{1p}^h} \\
\frac{\partial L_2(w)}{\partial w_{i0}^h} & \cdots & \frac{\partial L_2(w)}{\partial w_{ip}^h}
\end{bmatrix}
\]

\[
\Delta W^h = -\eta \cdot \sum_{D} \left[ ((W^o)T \delta^o) \odot y^h(x) \odot (1 - y^h(x))) \right]_{1,...,l} \otimes x
\]

\[
\delta^h
\]

Remarks:

- The symbol \( \odot \) denotes the Hadamard product, also known as the element-wise or the Schur product. It is a binary operation that takes two matrices of the same dimensions and produces another matrix of the same dimension as the operands, where each element is the product of the respective elements of the two original matrices. [Wikipedia]

- The symbol \( \otimes \) denotes the dyadic product, also called outer product or tensor product. The dyadic product takes two vectors and returns a second order tensor, called a dyadic in this context: \( v \otimes w \equiv vw^T \). [Wikipedia]

- \([W]_{1,...,l}\) denotes the projection operator, which returns the rows 1 through \( l \) of matrix \( W \) as a new matrix.

- \( \Delta W \) and \( \delta W \) indicate an update of the weight matrix per batch, \( D \), or per instance, \((x, c) \in D\), respectively.

Multilayer Perceptron at Arbitrary Depth

Network Architecture

Multilayer perceptron $y(x)$ with $d$ layers and $k$-dimensional output:

\[ x_0 = 1 \rightarrow \ldots \rightarrow y_0^1 = 1 \rightarrow \ldots \rightarrow y_0^{d-1} = 1 \rightarrow \ldots \rightarrow y_1 \rightarrow \ldots \rightarrow y_k \]

$x \in$ (extended input space)

$y^{h_1}$

Parameters $w$:

$W^{h_1} \in \mathbb{R}^{l_1 \times (p+1)}$

$y^{h_d} \equiv y \in \mathbb{R}^{k \times (l_{d-1}+1)}$
Multilayer Perceptron at Arbitrary Depth

(1) Forward Propagation

Multilayer perceptron $y(x)$ with $d$ layers and $k$-dimensional output:

\[
\begin{align*}
\mathbf{x} \in \text{extended input space} & \quad \rightarrow \quad \mathbf{y}^1 \rightarrow \cdots \rightarrow \mathbf{y}^{h_{d-1}} \rightarrow \mathbf{y}^d \\
& \quad \rightarrow \quad y_1 \rightarrow \cdots \rightarrow y_k
\end{align*}
\]

Parameters $w$:

\[
\begin{align*}
W^{h_1} & \in \mathbb{R}^{l_1 \times (p+1)} \\
W^{h_d} & \equiv W^o \in \mathbb{R}^{k \times (l_{d-1} + 1)}
\end{align*}
\]

Model function evaluation (= forward propagation):

\[
y^{h_d}(x) \equiv y(x) = \sigma \left( W^{h_d} y^{h_{d-1}}(x) \right) = \cdots = \sigma \left( W^{h_d} \left( \frac{1}{\sigma} \left( \cdots \left( \frac{1}{\sigma} \left( W^{h_1} \mathbf{x} \right) \cdots \right) \right) \right) \right)
\]

Learning rate, a small positive constant.

Output: \(W^{h_1}, \ldots, W^{h_d}\) Weight matrices of the \(d\) layers. (= hypothesis)

1. FOR \(s = 1\) TO \(d\) DO initialize\_random\_weights\((W^{h_s})\) ENDDO, \(t = 0\)
2. REPEAT
3. \(t = t + 1\)
4. FOREACH \((x, c) \in D\) DO
5. Model function evaluation.
6. Calculation of residual vector.
7a. Calculation of derivative of the loss.
7b. Parameter vector update \(\hat{=}\) one gradient step down.
8. ENDDO
9. UNTIL(convergence\((D, y(), t))\)
10. return\((W^{h_1}, \ldots, W^{h_d})\)

[Python code]
Remarks (derivation of $\nabla^h L_2(\mathbf{w})$):

- Partial derivative for a weight in a weight matrix $W^h$, $1 \leq s \leq d$:

$$
\frac{\partial}{\partial w^h_{ij}} L_2(\mathbf{w}) = \frac{\partial}{\partial w^h_{ij}} \frac{1}{2} \cdot \sum_{(x,c) \in D} \sum_{u=1}^{k} (c_u - y_u(x))^2 \\
= \frac{1}{2} \cdot \sum_{D} \sum_{u=1}^{k} \frac{\partial}{\partial w^h_{ij}} (c_u - y_u(x))^2 \\
= - \sum_{D} \sum_{u=1}^{k} (c_u - y_u(x)) \cdot \frac{\partial}{\partial w^h_{ij}} y_u(x) \\
\stackrel{(1,2)}{=} - \sum_{D} \sum_{u=1}^{k} (c_u - y_u(x)) \cdot y_u(x) \cdot (1 - y_u(x)) \cdot \frac{\partial}{\partial w^h_{ij}} W^h_u \cdot y^{h-1}(x) \\
\delta^h_u \equiv \delta^o_u \\
\stackrel{(3)}{=} - \sum_{D} \sum_{u=1}^{k} \delta^h_u \cdot \frac{\partial}{\partial w^h_{ij}} \sum_{v=0}^{l_{d-1}} w^h_{uv} \cdot y^{h-1}(x) \\
\delta^h_u \equiv \delta^o_u
$$

- Partial derivative for a weight in $W^d$ (output layer), i.e., $s = d$:

$$
\frac{\partial}{\partial w^d_{ij}} L_2(\mathbf{w}) = - \sum_{D} \sum_{u=1}^{k} \delta^d_u \cdot \sum_{v=0}^{l_{d-1}} \frac{\partial}{\partial w^d_{ij}} w^d_{uv} \cdot y^{h-1}(x) \quad \text{// Only for the term where } u = i \\
\text{and } v = j \text{ the partial derivative is nonzero. See the illustration.} \\
= - \sum_{D} \delta^d_i \cdot y^{h-1}(x)
$$
Remarks (derivation of $\nabla_h^s L_2(w)$) : (continued)

- **Partial derivative for a weight in a weight matrix $W^h_s$, $s \leq d-1$:**

  $$\frac{\partial}{\partial w^h_{ij}} L_2(w) = - \sum_D \sum_{l_d=1}^{k} \sum_{u=1}^{k} \sum_{v=0}^{l_d-1} \frac{\partial}{\partial w^h_{ij}} \; w^h_{uv} \cdot y^h_{v}(x) \cdot (1 - y^h_{v}(x)) \cdot \frac{\partial}{\partial w^h_{ij}} W^h_{v*} y^h_{v}(x)$$

  $(1,2)$

  $$= - \sum_D \sum_{l_d=1}^{k} \sum_{u=1}^{k} \sum_{v=1}^{l_d-1} \delta^h_u \cdot w^h_{uv} \cdot y^h_{v}(x) \cdot (1 - y^h_{v}(x)) \cdot \frac{\partial}{\partial w^h_{ij}} W^h_{v*} y^h_{v}(x)$$

  $(4)$

  $$= - \sum_D \sum_{l_d=1}^{k} \sum_{v=1}^{l_d-1} (W^h_{*v})^T \delta^h_v \cdot y^h_{v}(x) \cdot (1 - y^h_{v}(x)) \cdot \frac{\partial}{\partial w^h_{ij}} W^h_{v*} y^h_{v}(x)$$

  $(5)$

  $$= - \sum_D \sum_{l_d=1}^{k} \sum_{v=1}^{l_d-1} \delta^h_v \cdot \frac{\partial}{\partial w^h_{ij}} \sum_{w=0}^{l_d-2} w^h_{vw} \cdot y^h_{v}(x)$$

- **Partial derivative for a weight in $W^h_{d-1}$ (next to output layer), i.e., $s = d-1$:**

  $$\frac{\partial}{\partial w^h_{ij}} L_2(w) = - \sum_D \sum_{l_d=1}^{k} \sum_{v=1}^{l_d-1} \sum_{w=0}^{l_d-2} \frac{\partial}{\partial w^h_{ij}} \; w^h_{vw} \cdot y^h_{v}(x) \cdot (1 - y^h_{v}(x))$$

  Only for the term where $v = i$ and $w = j$ the partial derivative is nonzero.

  $$= - \sum_D \delta^h_i \cdot y^h_{j}(x)$$
Remarks (derivation of $\nabla^{h_s} L_2(w)$): (continued)

- Instead of writing out the recursion further, i.e., considering a weight matrix $W^{h_s}, \ s \leq d-2$, we substitute $s$ for $d-1$ (similarly: $s+1$ for $d$) to derive the general backpropagation rule:

$$\frac{\partial}{\partial w_{ij}^{h_s}} L_2(w) = - \sum_D \delta_i^{h_s} \cdot y_j^{h_{s-1}}(x) \ // \ \delta_i^{h_s} \text{ is expanded based on the definition of } \delta_v^{h_{d-1}}.$$  

$$= - \sum_D (W^{h_s+1}^* \delta^{h_{s+1}} \cdot y_i^{h_s}(x) \cdot (1 - y_i^{h_s}(x)) \cdot y_j^{h_{s-1}}(x)$$

- Plugging the result for $\frac{\partial}{\partial w_{ij}^{h_s}} L_2(w)$ into $-\eta \cdot \cdots$ yields the update formula for $\Delta W^{h_s}$. In detail:

  - For updating the output matrix, $W^{h_d} \equiv W^0$, we compute

    $$\delta^{h_d} = (c - y(x)) \odot y(x) \odot (1 - y(x))$$

  - For updating a matrix $W^{h_s}, 1 \leq s < d$, we compute

    $$\delta^{h_s} = \left[ (W^{h_{s+1}})^T \delta^{h_{s+1}} \cdot y^{h_s}(x) \cdot (1 - y^{h_s}(x)) \right]_{1, \ldots, l_s}, \ \text{where} \ \ W^{h_{s+1}} \in \mathbb{R}^{l_{s+1} \times (l_s+1)}, \ \delta^{h_{s+1}} \in \mathbb{R}^{l_{s+1}}, \ \ y^{h_s} \in \mathbb{R}^{l_s+1}, \ \text{and} \ \ y^{h_0}(x) \equiv x.
Remarks (derivation of $\nabla^h L_2(w)$) : (continued)

Hints:

(1) $y_u(x) = \left[ \sigma \left( W^h y^{h-1}(x) \right) \right]_u = \sigma \left( W^h y^{h-1}(x) \right)$

(2) Chain rule with $\frac{d}{dz} \sigma(z) = \sigma(z) \cdot (1 - \sigma(z))$, where $\sigma(z) := y_u(x)$ and $z = W^h y^{h-1}(x)$:

$$\frac{\partial}{\partial w_{ij}^h} y_u(x) \equiv \frac{\partial}{\partial w_{ij}^h} \left( \sigma \left( W^h y^{h-1}(x) \right) \right) \equiv \frac{\partial}{\partial w_{ij}^h} \left( \sigma \left( z \right) \right) = y_u(x) \cdot (1 - y_u(x)) \cdot \frac{\partial}{\partial w_{ij}^h} \left( W^h y^{h-1}(x) \right)$$

Note that in the partial derivative expression the symbol $x$ is a constant, while $w_{ij}^h$ is the variable whose effect on the change of the loss $L_2$ (at input $x$) is computed.

(3) $W^h u^*_d y^{h-1}(x) = w^h u^*_d y^{h-1}(x) + \ldots + w^h j y^{h-1}(x) + \ldots + w_{ul}^h l^{h-1} y^{h-1}(x)$, where $l^{h-1} = no._{rows}(W^h)$.  

(4) Rearrange sums to reflect the nested dependencies that develop naturally from the backpropagation. We now can define $\delta^{h-1}_{v}$ in layer $d-1$ as a function of $\delta^h$ (layer $d$).

$$\sum_{u=1}^k \delta^h_u \cdot w^h_{uv} = (W^h_{*v})^T \delta^h$$ (scalar product).
Remarks (derivation of $\nabla^h L_2(w)$) : (continued)

- $y(x)$ as a function of some $w^h_{ij}$ in the output layer $W^o$ and some middle layer $W^h$. To calculate the partial derivative of $y_u(x)$ with respect to $w^h_{ij}$, determine those terms in $y_u(x)$ that depend on $w^h_{ij}$ (shown orange). All other terms are in the role of constants.

$$y_u(x) = \left[ \sigma \left( W^h \left( \sigma \left( \ldots \left( \sigma \left( W^{h+1} \left( \sigma \left( W^h \left( y_{h-1}(x) \right) \right) \right) \ldots \right) \ldots \right) \ldots \right) \right) \right) \right]_u$$

- Compare the above illustration to the multilayer perceptron network architecture.
Remarks (derivation of $\nabla^h_s L_2(w)$): (continued)

- $y(x)$ as a function of some $w^h_{ij}$ in the output layer $W^o$ and some middle layer $W^h_s$. To calculate the partial derivative of $y_u(x)$ with respect to $w^h_{ij}$, determine those terms in $y_u(x)$ that depend on $w^h_{ij}$ (shown orange). All other terms are in the role of constants.

$$y_u(x) = \left[ \sigma \left( W^h_d \left( \sigma \left( \cdots \left( \sigma \left( W^h_{s+1} \left( \sigma \left( W^h_s y^{h_{s-1}}(x) \right) \right) \right) \cdots \right) \right) \right) \right) \right]_u$$

- Compare the above illustration to the multilayer perceptron network architecture.
Remarks (derivation of $\nabla^o L_2(w)$ and $\nabla^h L_2(w)$ for MLP at depth one):

- $\nabla^o L_2(w) \equiv \nabla^h L_2(w)$, and hence $\delta^o \equiv \delta^h$.

- $\nabla^h L_2(w)$ is a special case of the $s$-layer case, and we obtain $\delta^h$ from $\delta^{hs}$ by applying the following identities:
  \[ W^{hs+1} = W^o, \quad \delta^{hs+1} = \delta^h = \delta^o, \quad y^{hs} = y^h, \quad \text{and} \quad l_s = l. \]
